

FIN 330: Midterm Exam

Fall 2024

Professor Bjørn Eraker
Wisconsin School of Business

Name: John Doe

Campus ID: 1234567890

Section: 101

Instructions

- This is a closed-book, closed-note exam. You are allowed to use your pens/pencils, your calculator only.
- A formula sheet is attached to the back of the exam. If you remove the formula sheet during the exam, please ensure that the stapling of the exam portion of this document remains intact.
- Show all your work in a well-organized fashion if you wish to get full credit.
- Use legible handwriting. If we can't read what you have written, it will not count.
- When you exit the classroom, please refrain from speaking to other students.

$$F = \{FF \rightarrow S\} \rightarrow f + S +$$

I understand and agree to abide by the exam instructions listed above.

Date: _____

FIN 3303: Financial Markets

Exam 1

1. You receive \$6000 in 185 days from now. Assume a 365 day-per-year convention and compute the present value using continuous compounding with a 4.5% discount rate.

$$6000 e^{-0.045 \cdot \frac{185}{365}} \approx 5864.70$$

2. You sell (short) a European Put with strike 75. On the expiration date the underlying stock is at 65. What is your payoff?

an option payoff

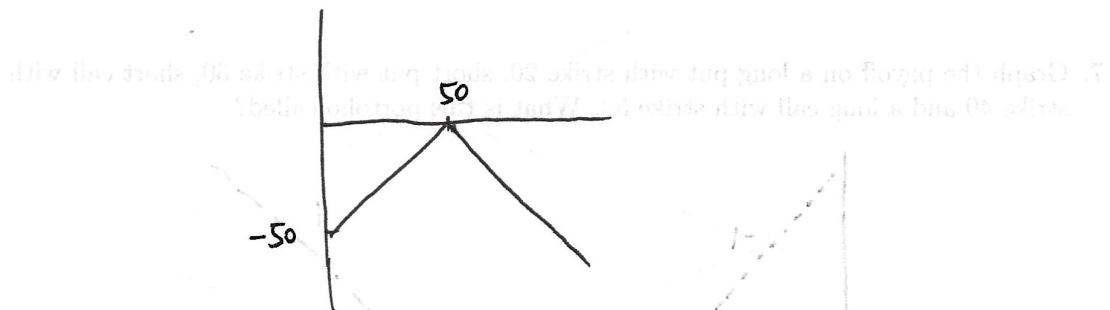

$$-\max\{75 - 65, 0\} = -10$$

problem having to do with a put option payoff. The payoff is zero if the stock price is above the strike price. It is the difference between the strike price and the stock price if the stock price is below the strike price.

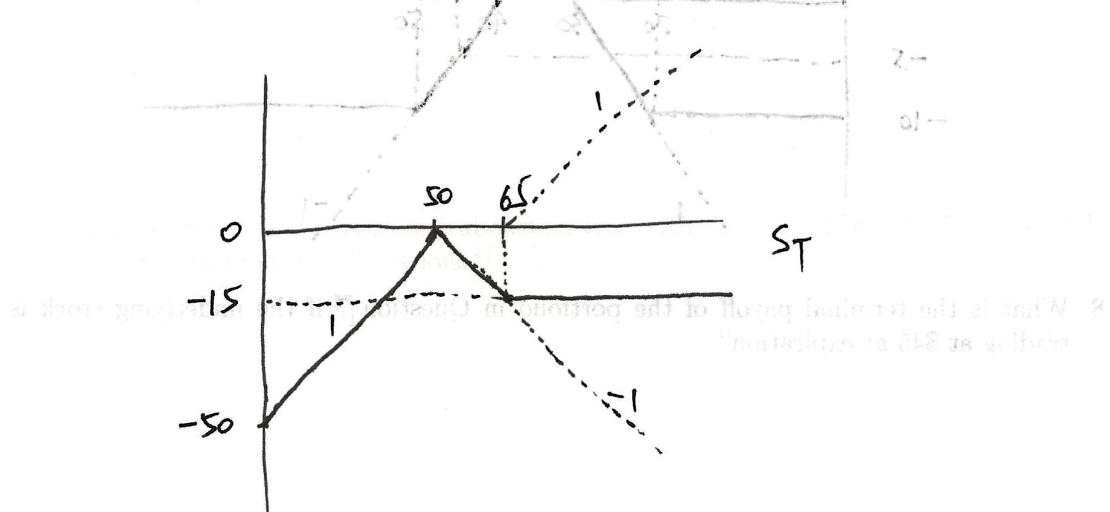

3. You sell a straddle with strike 77. The price of the put is \$3 and the call is \$4. On the expiration date the underlying stock is at 63. What is your profit?

$$+3 + 4 - |63 - 77| = -7$$

4. You sell a straddle with strike 50. Graph the payoff on this portfolio.

5. Graph the payoff to a short straddle with strike 50 and a long call with strike 65.

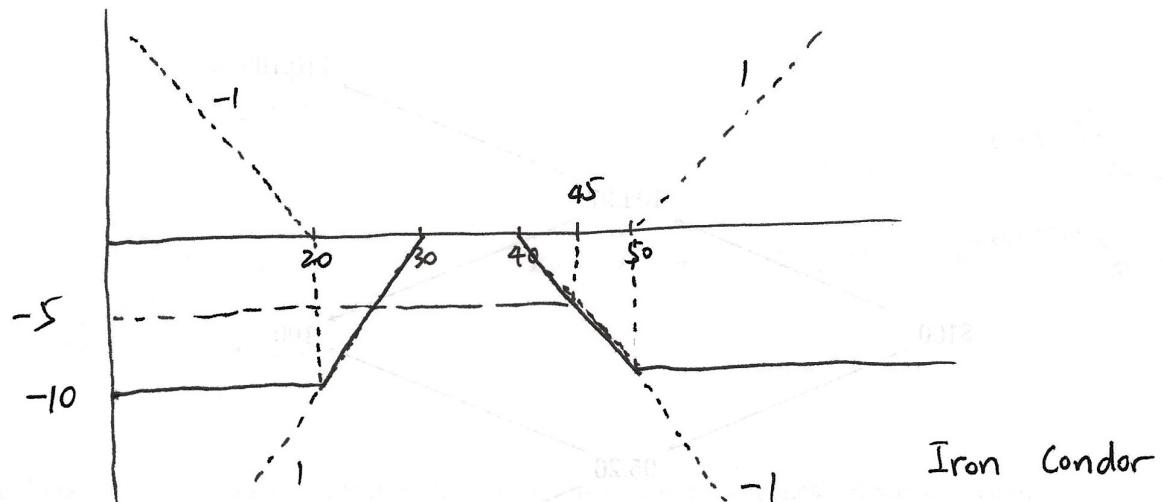

6. What is the maximum loss on the trade in the previous question?

$$(-50 - 25)^2 \times 0.1 + (0.25 - 25^2) \times 0.1 = (0.25 - 625) \times 0.1 = (0.25 - 625) \times 0.1 = -50$$

$$25 - 50 + 25 - 50 - 50 = -50$$

7. Graph the payoff on a long put with strike 20, short put with strike 30, short call with strike 40 and a long call with strike 50. What is this portfolio called?

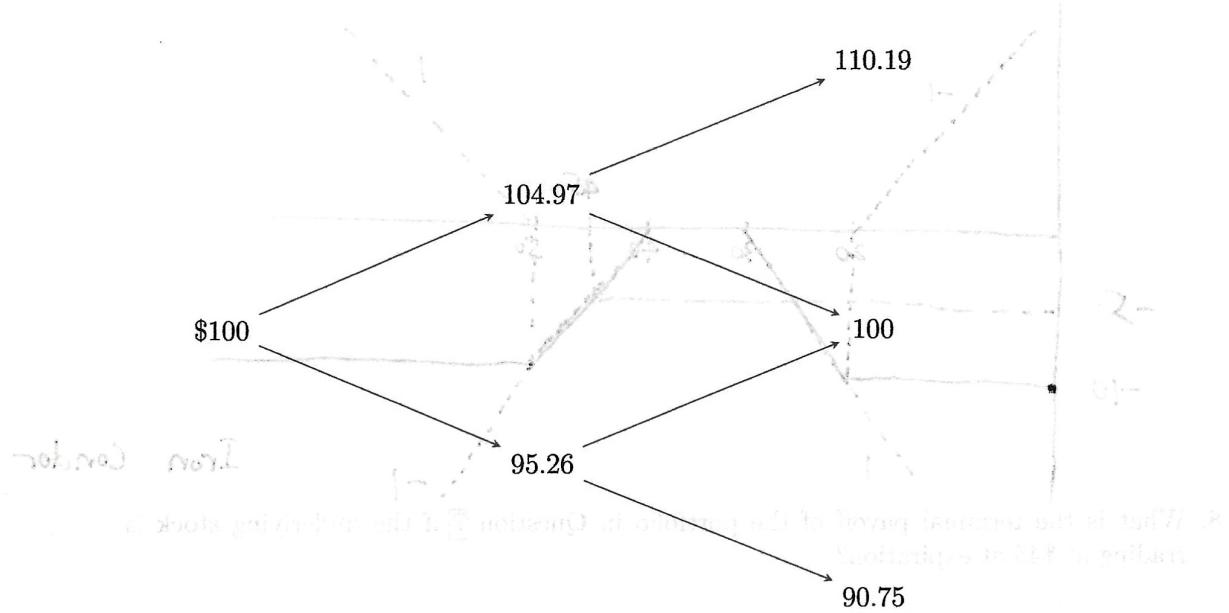

8. What is the terminal payoff of the portfolio in Question 7 if the underlying stock is trading at \$45 at expiration?

$$\begin{aligned}
 & \text{Max}\{20 - 45, 0\} - \text{Max}\{30 - 45, 0\} - \text{Max}\{45 - 40, 0\} + \text{Max}\{45 - 50, 0\} \\
 &= 0 - 0 - 5 + 0 = -5
 \end{aligned}$$

$b = 45$

$$\text{Gamma} = \frac{\frac{1}{45-20}}{b-\omega} = \frac{\frac{1}{25}}{45-\omega} = \frac{1}{25(45-\omega)} = q$$

After this node, the call option price will be $\max(0, 110.19 - 100)$. These q salt deposit
Stock price will be $110.19 \cdot 0.95 = 104.97$

The above tree is a Cox-Ross-Rubenstein tree with $\Delta t = 1/52$, $r = 0.05$, $\sigma = 0.35$ Use these values to answer Questions 9 - 11.

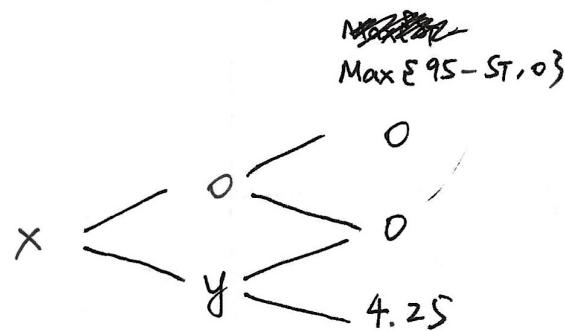

$$\{u, d\}^2 = \{u^2, 2ud, d^2\} \text{ and } \{u, d\}^3 = \{u^3, 3u^2d, 3ud^2, d^3\}$$

$$u = e^{\frac{\sigma \sqrt{\Delta t}}{2}} = e^{0.35 \cdot \frac{1}{\sqrt{52}}} = 1.207$$

$$d = \frac{1}{u}$$

$$p = \frac{e^{r\Delta t} - d}{u - d} = \frac{e^{0.05 \cdot \frac{1}{52}} - d}{u - d} \approx 0.49777$$

9. Use the Binomial tree to compute the value of a European Put option with strike 95.

$$y = (p \cdot 0 + (1-p) \cdot 4.25) \cdot e^{-0.05 \cdot \frac{1}{52}} \approx 2.133$$

$$x = (p \cdot 0 + (1-p) \cdot 2.133) \cdot e^{-0.05 \cdot \frac{1}{52}} \approx 1.07$$

10. Find the value of a European Put with strike 95 using the easiest method you can think of.

Call

put call parity:

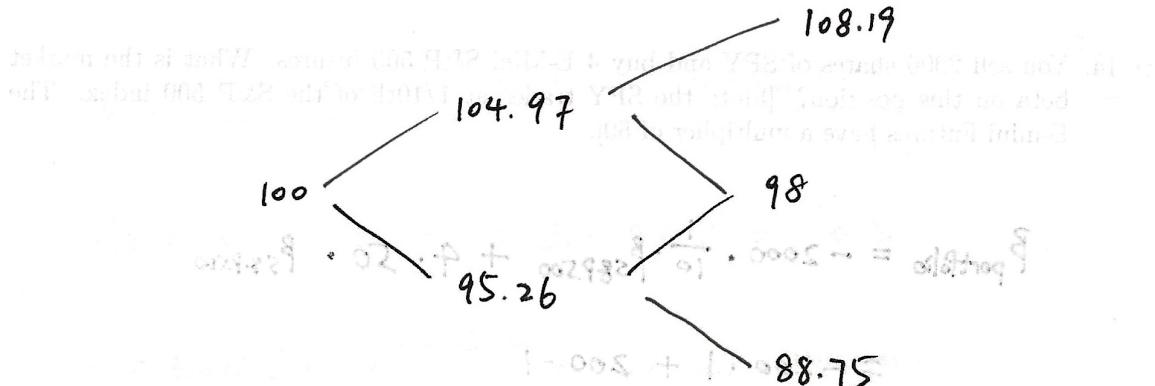

~~RECALL CALL PRICE~~

$$\text{by } C = P + S - Ke^{-rT}$$

$$= 1.07 + 100 - 95e^{-0.05 \cdot \frac{2}{52}}$$

$$\approx 6.253$$

11. Assume that the stock above pays a \$2 dividend in the final period. Adjust the tree to account for this.

12. Given the dividend-adjusted tree above in Question 11, is it ever optimal to exercise the American call early?

$$\Delta \quad x = \max\left\{ (p \cdot 13.19 + (1-p) \cdot 3) e^{-0.05 \cdot \frac{1}{52}}, 104.97 - 95 \right\}$$

$$= \max\{ 8.065, 9.97 \} = 9.97 \quad (E)$$

Exercise $\max\{S_T - 95, 0\}$

$$\Delta \quad y = \max\left\{ (p \cdot 3 + (1-p) \cdot 0) e^{-0.05 \cdot \frac{1}{52}}, 95.26 - 95 \right\}$$

$$= \max\{ 1.492, 0.26 \} = 1.492 \quad (NE)$$

$$\Delta \quad z = \max\left\{ (p \cdot x + (1-p) \cdot y) e^{-0.05 \cdot \frac{1}{52}}, 100 - 95 \right\}$$

$$= \max\{ 5.707, 5 \} = 5.707 \quad (N\bar{E})$$

13. The S&P index is at 4400. The continuous compounding interest rate is at 4.3%, and the dividend yield on the S&P 500 is 1.7%. What is the futures price for 6 month maturity S&P 500 futures?

$$F_t = S_t e^{(r-q)(T-t)} = 4400 e^{(0.043 - 0.017) \cdot \frac{6}{12}} \approx 4457.57$$

of went out hand & I'm going to do it again. I'm going to do it again.

PI.801

14. You sell 2000 shares of SPY and buy 4 E-Mini S&P 500 futures. What is the market beta on this position? [hint: the SPY trades at 1/10th of the S&P 500 index. The E-mini Futures have a multiplier of 50].

$$\begin{aligned}\beta_{\text{portfolio}} &= -2000 \cdot \frac{1}{10} \cdot \beta_{\text{S&P500}} + 4 \cdot 50 \cdot \beta_{\text{S&P500}} \\ &= -200 \cdot 1 + 200 \cdot 1 \\ &= 0\end{aligned}$$

and we're going to do it again. I'm going to do it again.

- (3) 15. Consider the SPY and E-mini position from the previous question again. Assume that interest rates go down 100BPS (1%). Will you make or lose money? Assume that Futures-spot-parity holds. Verbal answer: 5 points: Quantitative answer by plugging into parity formula: 8 points. Analytical answer using calculus: 10 points.

$$\begin{aligned}(3V) FOF.1 &= (S_{t0} \cdot FOF.1)^{200} \\ &= 200 \cdot \frac{\partial (F_t - S_t)}{\partial r} \cdot \Delta r \\ (3W) FOF.2 &= 200 \cdot \frac{\partial (S_t e^{r(T-t)} - S_t)}{\partial r} \cdot (-1\%)\\ &= -2 \cdot S_t (T-t) e^{r(T-t)} < 0\end{aligned}$$

f2. f2 + 1 =
lose money
 $\frac{\partial}{\partial r} (F_{t0} - S_{t0})$

16. Find the price of a European Call option with initial stock price $S_0 = 300$, strike $K = 300$, interest rate $r = 0.05$, volatility $\sigma = 0.4$ and time to maturity of four years $T - t = 4$ using the Black-Scholes model.

$$d_1 = \frac{\ln(\frac{S_t}{K}) + (r + \frac{1}{2}\sigma^2)(T-t)}{\sigma\sqrt{T-t}} = \frac{\ln(\frac{300}{300}) + (0.05 + \frac{1}{2} \cdot 0.4^2) \cdot 4}{0.4\sqrt{4}} = 0.65$$

$$d_2 = d_1 - \sigma\sqrt{T-t} = d_1 - 0.4\sqrt{4} = -0.15$$

$$C = 300 \cdot N(d_1) - e^{-0.05 \cdot 4} \cdot 300 \cdot N(d_2) = 114.48$$

17. Without doing any math, would the European option in Question 16 be worth more or less if the underlying stock pays a \$10 dividend each year before expiration?

Less

$$\text{in case w/ } (R - r_d) > 0 \text{, option is worth more}$$

$$(r_d)_{\text{real}} = \mathbb{E}^{\pi}[(R - r_d)] \geq \mathbb{E}[(R_{\text{real}}) - r_d]$$

18. Suppose you can borrow in Yen (JPY) at 0.5% and invest in the US at 4.5%. Explain how to exploit this 1) by borrowing in Yen and investing in the US, and 2) by entering a futures contract on JPY. Are the two equivalent?

18. A call option with $S_0 = \$20$ and payoff $\max(S_T - K, 0)$ is sold at price $C = \$1$. If the stock price S_T is uniformly distributed between $K = \$10$ and $S_0 = \$20$, what is the expected payoff?

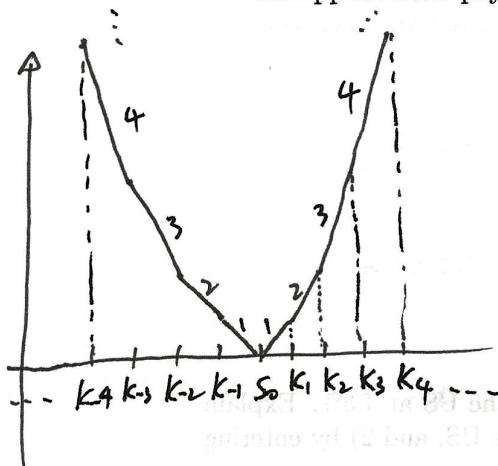

19. Suppose the Japanese central bank (Bank of Japan) increases rates unexpectedly to 1%. This leads to an increase of 1.5% in the JPY/USD spot exchange rate. Name two ways in which the futures trade from the previous question makes or loses money.

$$Z_{1,0} = P_{1,0} - h \approx 1.01 - 1.00 = \$0$$

$$\text{PP}_{1,0} = (\delta)U_{\text{out}} + (1-\delta)U_{\text{in}} = 1.01U_{\text{out}} - 1.00U_{\text{in}} = 1$$

to whom it is most likely to be repaid with interest. At the same time, the risk of default is also reduced since the cash flow is more predictable than a loan.

20. Graph the payoff to a portfolio that buys every out-of-the-money PUT and CALL option with strikes K_1, K_2, \dots, K_n and state what the slopes are between each strike. What is the approximate payoff? What is the interpretation of the portfolio?

Approximate payoff: $a(S_T - S_0)^2$ for some a
 invest $\frac{1}{a}$

Variance Payoff: payoff proportional to variance of
 the underlying stock
